Reanalysis of 06-Wile

Simon Schwab

13/05/2020

Reference

Wile et al. (2017). Serotonin and dopamine transporter PET changes in the premotor phase of LRRK2 parkinsonism: cross-sectional studies. *Lancet Neurology*, 16(5), 351–359. https://doi.org/10.1016/S1474-4422(17)30056-X

Notes from reading methods section

- Dependant variable: PET radiotracer called 11C-DASB in cortex (first of many ANCOVAs reported)
- Independant variable: Group
 - Healty controls (n=9)
 - LRRK2 w/o PD (n=9)
 - LRRK2 w PD (n=7)
 - sporadic PD (n=13)
- Covariate: age
- age was not estimable for LRRK2 without manifest Parkinson's disease
- Design: 4-way ANCOVA with group as IV and age as covariate

Reading data

Data is loaded, reshaped if necessary, and factors are specified.

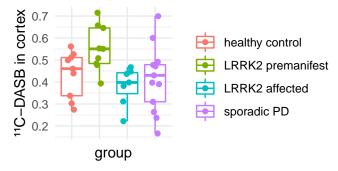

Descriptives

Dependant variable

Number of samples and mean (SD) in levels of the independant variables. We reproduce Table 3 and Figure 2A of the study.

```
idx = c(1, 3, 2, 4) # sorting as in publication
tab.dv = array(NA, dim=c(4,3))
tab.dv[,1] = levels(data$Group.factor)
tab.dv[,2] = summary(data$Group.factor)
tab.dv[,3] = tapply(data$Cortex, data$Group.factor,
                  function (x) sprintf(\%0.2f(\%0.2f)), mean(x), sd(x))
colnames(tab.dv) = c("group", "n", "mean (SD)")
print(tab.dv)
##
        group
                                 mean (SD)

ANCOVA

We will use Type I sum of squares for balanced designs (equal n per group), and Type III for unbalanced designs and used in SAS and SPSS.

```
contrasts(data$Group.factor) = contr.helmert(4) # when is this necessary?
fit = aov(Cortex ~ `Age at PET` + Group.factor, data = data)
# result = summary(fit) # Type I
result = Anova(fit, type=3) # Type III
print(result)
## Anova Table (Type III tests)
## Response: Cortex
                 Sum Sq Df F value
                                     Pr(>F)
## (Intercept) 0.36361 1 25.1466 1.767e-05 ***
## `Age at PET` 0.00073 1 0.0502
                                     0.8241
## Group.factor 0.12125 3 2.7951
                                     0.0555 .
## Residuals
               0.47717 33
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
# stats.reanalysis = data.frame(Fvalue = sprintf("%.2f",result[[1]]$`F value`[1]),
#
                                df1 = result[[1]] Df[1],
#
                               df2 = result[[1]] Df[2],
#
                               pvalue = formatPval(result[[1]]$`Pr(>F)`[1]))
```

Comparing ANCOVA in original study with reanalysis

Independent variable

Covariate

df1 ## df2

pvalue NA

```
tab.CV = rbind(stats.orig.CV, stats.rep.CV)
rownames(tab.CV) = c("original Study", "reanalysis")
print(t(tab.CV))

## original Study reanalysis
## Fvalue NA "0.05"
```

Assumptions

NA

1. Homogeneity of variance

" 1"

"33"

"0.82"

- ANOVA/ANCOVA is fairly robust in terms of the error rate when sample sizes are equal.
- When groups with larger sample sizes have larger variances than the groups with smaller sample sizes, the resulting F-ratio tends to be conservative. That is, it's more likely to produce a non-significant result when a genuine difference does exist in the population.
- Conversely, when the groups with larger sample sizes have smaller variances than the groups with smaller samples sizes, the resulting F-ratio tends to be liberal and can inflate the false positive rate.

```
tapply(data$Cortex, data$Group.factor, sd)
                                           LRRK2 affected
##
     healthy control LRRK2 premanifest
                                                                 sporadic PD
          0.10480960
                            0.10221440
                                               0.08699411
                                                                  0.14748558
##
leveneTest(Cortex ~ Group.factor, data = data)
## Levene's Test for Homogeneity of Variance (center = median)
         Df F value Pr(>F)
              0.821 0.4914
## group 3
##
         34
```

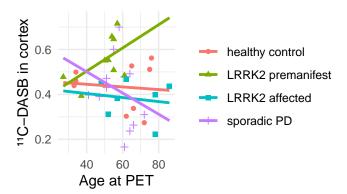

2. Independence between covariate and IV

When the covariate and the experimental effect (independent variable) are not independent the treatment effect is obscured, spurious treatment effects can arise and the interpretation of the ANCOVA is seriously compromised.

We test whether our groups differ on the CV. If the groups do not significantly differ then is appropriate to use the covariate.

3. Homogeneity of regression slopes

```
fit.hrs = aov(Cortex ~ `Age at PET`*Group.factor, data = data)
Anova(fit.hrs, type=3)
## Anova Table (Type III tests)
##
## Response: Cortex
##
                             Sum Sq Df F value
                                                  Pr(>F)
## (Intercept)
                             0.31357 1 21.8078 5.908e-05 ***
## 'Age at PET'
                             0.00032 1
                                        0.0226
                                                   0.8816
## Group.factor
                             0.02337
                                     3 0.5417
                                                   0.6574
## `Age at PET`:Group.factor 0.04580 3
                                        1.0617
                                                   0.3800

```

Additional analyses: MANCOVA

The paper performed four ANCOVAs for cortex, striatum, brainstem, and hypothalamus but did not correct for multiple testing. Therefore, we also perform a MANCOVA.

```
fit = manova(cbind(Cortex, Striatum, Brainstem, Hypothalamus) ~ Group.factor + `Age at PET`, data=data)
summary(fit)
```

```
